(54) Title: IC CARD SYSTEM

(57) Abstract

An IC information card includes a programmed microprocessor and a nonvolatile read/write memory (EPROM) embedded in a plastic card. Terminal contacts on the face of the card enable interfacing with a reader/writer coupled to a host computer, such as an IBM-XT. The data storage portion of the memory in the card is segmentable into one or more data zones, each requiring either no access code or one or more access codes to be entered in the card in order to access (read and/or write) that zone. Segmentation of the card memory and the assignment of required access codes is achieved by writing a zone definition table and one or more access codes into the card memory using a special access code that is fixed in the microprocessor program. The access codes for the data zones are thus stored on the card and the programmed microprocessor in the card compares incoming codes to the stored codes to determine whether access to a particular data zone is permissible. The access codes for the data zones of the card memory are advantageously stored in a control card, which is interfaced to a two-card reader/writer together with the card to be accessed. In this manner, the required access codes are transferred from the control card to the information card when access of a data zone therein is required, and the access codes stored in the control card need not become known to any individual. The card is locked upon failure to receive a proper access code a predetermined number of times in succession, but can be unlocked up to a certain number of times by providing an unlocking code in combination with prespecified access codes. An initializer system initializes the cards by writing a zone definition table and one or more access codes in the card memory and by reading a file identification code prewritten on a magnetic stripe of the card. The file identification code is used to locate a corresponding data file in a mass storage device associated with the computer. The data in the corresponding data file are then written into appropriate data zones of the memory of the card.

DescriptionIC Card SystemTechnical Field

A microfiche appendix containing 145 frames on
5 2 cards is included in the specification and is
hereafter referred to as Appendix I.

Background of the Invention

The present invention relates to an integrated
circuit (IC) information card system using a card
10 having an integrated circuit chip or chips including a
programmable processor and a nonvolatile read/write
memory for storing data and access codes needed to
access the data.

Various types of information cards have been
15 developed which include storage media for storing
information identifying the user of the card and other
information. One such card is the ordinary plastic
credit card or identification card which has embossed
lettering on the card to indicate the identity of the
20 holder, an identification or account number and
possibly other information. In addition, the ordinary
plastic credit or identification card has on its
backside a magnetic stripe for magnetically storing
data. The data stored on the magnetic strip typically
25 verifies the embossed information on the front of the
card and includes additional information. Such
magnetic stripe plastic cards, while inexpensive to
manufacture and issue, provide relatively little
security against unauthorized or fraudulent access
30 to the information stored on the exposed magnetic
stripe, since such information can be easily read or
altered using commonly available equipment.
Furthermore, the recorded data on the magnetic stripe
may be distorted or destroyed by dirt, scratches or
35 contact of the magnetic stripe with magnetic materials
. Moreover, the capacity of such a magnetic stripe

plastic card is limited to about 0.5K bits to 1.7K bits, or about 70 to 200 alphanumeric characters.

Another type of card, known as the laser card, is similar to the magnetic-stripe plastic card but
5 replaces the magnetic stripe with a stripe of reflective material. Information is stored in the laser card by burning microscopic holes in the surface of the reflective stripe with a focused, low-power laser. Although the laser card is capable of very
10 high data storage capacities of up to 1 million bits, it also does not provide adequate protection against unauthorized access to the data stored in the exposed reflective stripe, which can be easily read or written using the proper equipment.

15 Yet another type of information card incorporates integrated circuit memory of either the read only and the write/read variety. Such a memory card typically has multiple electrical contacts located at one or more edges of the card or on a face of the card to
20 permit electrical access to the address, data and any control terminals of the memory in the card. However, such memory cards generally provide relatively little or no protection against unauthorized access to the data stored in the card, since the contents of the
25 card memory can, in most cases, be easily read out or added to with the proper equipment. Further, some memory cards use volatile memory requiring a costly, built-in, power source in the card to prevent loss of the data stored in the card memory. The foregoing
30 deficiencies of memory cards have essentially limited their use.

Still another type of information card, known as the wired-logic card, incorporates an integrated hard-wired logic circuit together with nonvolatile
35 integrated circuit memory to provide improved security for the data stored in the memory. In such a card, access to the memory may be entirely under the control of the hard-wired logic circuit, which may require the

entry of a secret code or key before access to the memory is permitted. Owing to the limited processing capability of the hard-wired logic circuit, the wired-logic cards have been limited to relatively simple applications, such as for telephone payments and records.

The latest generation of information cards, which are commonly referred to as "intelligent" or "smart" cards, includes a programmable integrated circuit processor together with nonvolatile integrated circuit memory within the card. Since the programmable processor provides greatly expanded processing capabilities, the card may incorporate a sophisticated security system to prevent unauthorized or fraudulent access to some or all of the data stored in the card memory.

One such security system is disclosed and claimed in U.S. Patent No. 4,211,919 to Michael Ugon, which issued on July 8, 1980. In that security system, the card memory is segmented into three particular zones, namely: a secret zone in which reading and writing operations are permitted only by the internal processor of the card; a working zone in which reading and writing operations are permitted directly by an external card reader/writer device; and a read zone in which only reading operations are permitted directly by the card reader/writer device. The secret zone of the card memory includes at least one key or code which is compared to a key received from a card reader/writer device to determine whether a particular access operation to the working zone is authorized.

The above-described card security system has the problem in that data segments of the working zone may be defined only in the application program of the host computer of the card system, therefore adding to the complexity of such an application program. Furthermore, all data in the working zone have only a single security level for reading and writing

operations, respectively, i.e., with the entry of the proper key or combination of keys the entire working zone may be read or written.

In many applications for information cards, it is
5 desirable to have the flexibility of being able to define the data zones of the card memory within the card itself and of being able to assign different security levels for reading or writing operations in the various data zones to suit the particular
10 application. For example, in a health care application where the card is used to store data concerning a health care recipient, it would be appropriate to restrict access to certain categories of data only to particular classifications of health care personnel
15 (e.g., doctors, pharmacists, etc.) and to similarly restrict the authority to add or alter the data in the card memory. Therefore, it is desirable to store the various categories of data concerning the health care recipient in different zones of the card memory as
20 defined within the card and to assign an appropriate access security level, based on one or more access keys, for reading and writing operations to each data zone.

Accordingly, a need clearly exists for an IC card
25 structure and method in which the card memory may be segmented into a desired number of data zones after this card is manufactured and in which each data zone of the card memory may be assigned a respective security level, based on one or more access keys, for
30 reading or writing operations in that zone. A system using an IC card and method may advantageously include provisions for preventing the dissemination of knowledge of the access keys or combinations of such keys which define the security levels for the data
35 zones of the card memory and for initializing the cards (i.e., defining the data zones of the card memory, assigning respective security levels to each data zone and loading the proper data into the various

data zones card of the care memory) for each application on a mass production basis.

Summary of the Invention

In accordance with the present invention, an IC information card, systems for using and initializing such cards and methods for segmenting the card memory and for preventing the dissemination of knowledge of access codes are provided which overcome or at least mitigate the limitations and problems of the prior art as described above.

The IC information card in accordance with the present invention comprises input/output means in the card for receiving at least data, commands and keycodes and for providing at least data. In addition, the card includes nonvolatile read/write memory means within the card, the memory means having a multiplicity of addressable bit storage locations. Furthermore, the card includes first means within the card responsive to a first command, zone definition data and an entered keycode received by the input/output means for comparing the entered keycode with a first keycode stored in the card and for writing the zone definition data in a first region of the memory means only if the received keycode matches the first keycode, the zone definition data comprising one or more zone definition words each corresponding to a respective data zone in a second region of the memory means, each zone definition word specifying at least the starting address of the corresponding data zone and the size of the corresponding data zone.

Security levels may be specified for each of the data zones by providing the card with second means responsive to a second command, keycode data comprising one or more additional keycodes and an entered keycode received by the input/output means for comparing the entered keycode with the first keycode and for writing the additional keycodes in a third region of the memory means only if the entered keycode

matches the first keycode, and having each zone definition word further specify either no keycode or one or more of the first keycode and the additional keycode or keycodes as being required to be received
5 by the input/output means in order to read data from the corresponding zone and either no keycode or one or more of the first keycode and the additional keycode or keycodes as being required to be received by the input/output means in order to write data in the
10 corresponding data zone.

In the preferred embodiment of the IC information card there is provided a third means within the card responsive to a read command, a code specifying a particular one of the data zones from which data is to
15 be read and any entered keycode or keycodes received by the input/output means for comparing any entered keycode or keycodes with any keycode or keycodes specified as being required to read data in the particular data zone for providing data from the
20 particular zone to the input/output means if the entered keycode or keycodes match the keycode or keycodes specified as being required to read data from the particular data zone or if no keycode is specified as being required to read data from the particular
25 data zone. Also provided in the preferred embodiment is a fourth means within the card responsive to a write command, a code specifying a selected one of the data zones in which data is to be written, data is to be written in the selected zone and any entered
30 keycode or keycodes received by the input/output means for comparing any entered keycode or keycodes with any keycode or keycodes specified as being required to write data in the selected data zone and for writing the received data in the selected data zone if the
35 entered keycode or keycodes match the keycode or keycodes specified as being required to write data in the selected data zone or if no keycode is specified

as being required to write data in the selected data zone.

Moreover, in the preferred embodiment of the IC information card data is stored in each data zone as successively located data records and each zone definition word further specifies the maximum number of data records that can be stored in the corresponding zone, the length of the data in each data record in the corresponding zone and a zone allocation area in the memory means for storing data indicative of the location of the next data record to be stored in the corresponding zone. Each data record stored in a data zone includes a checksum byte and a record status byte indicative of the validity of the data record. In addition, each zone definition word further specifies whether the data provided to the input/output means by the third means in response to a read command and a code specifying data to be read from the corresponding zone is only the last data record to be written in the corresponding zone or all data records that are stored in the corresponding zone in the order in which such data records are written in the corresponding zone.

An additional feature of the preferred embodiment of the IC information card in accordance with the present invention is the "locking" of the card after a specified number of successive unsuccessful attempts to access the card. This feature is implemented in the following manner. The memory means further contains a plurality of successively ordered lock status words, including a first and a last lock status word, each lock status word having a predetermined number of successively ordered bit positions, including a first and a last bit position, each bit position of each lock status word being initially in a second binary state. Additionally, the card further comprises fifth means within the card responsive to a failure of an entered keycode to match a keycode

stored in the card, as a result of a keycode comparison made by the first, second, third or fourth means, for writing a first binary state in the lowest order bit position that is in the second binary state of the
5 lowest order lock status word in which the highest order bit position is in the second binary state. The fifth means is responsive to a match of an entered keycode with a keycode stored in the card occurring directly after a failure of an entered keycode to
10 match a keycode stored in the card, as a result of a comparison made by the first, second, third or fourth means, for writing a first binary state in the highest order bit position of the lock status word in which a first binary state was written by the fifth means in
15 response to the directly preceding failure of an entered keycode to match a keycode stored in the card. The card further comprises sixth means within the card responsive to a lock status word having all but its highest order bit position in the first binary state
20 for placing the card in a locked state in which at least reading and writing access to the first and second regions of the memory are prevented. Lastly, the card includes seventh means within the card responsive to an unlock command and one or more
25 entered keycodes for comparing the entered keycode or keycodes with preselected keycode or keycodes stored in the card and for writing a first binary state in the highest order bit position of the lock status word having all but the highest order bit position in the
30 first binary state to release the card from the locked state, if the entered keycode or keycodes match the preselected keycode or keycodes.

In the preferred embodiment of the IC information card in accordance with the invention, the first,
35 second, third, fourth, fifth, sixth and seventh means are included in an appropriately programmed microprocessor operatively coupled to the input/output means, and the memory means includes a programmable

read-only memory operatively coupled to the microprocessor.

The above-described IC information card in accordance with the invention is advantageously used in conjunction with two-card reader/writer means having a first and a second port for receiving a first and a second card, respectively, and for coupling to the input/output means thereof, coupling means for receiving at least commands, data and keycodes and for providing at least data, and reader/writer memory means. The reader/writer means further includes first means responsive to the coupling means receiving a command to read the second card, a code specifying a particular zone in the second card from which data is to be read and any keycode or keycodes to be entered in the first card, for providing to the input/output means of the first card one or more read commands together with a code or codes specifying the data zone or zones of the memory means of the first card where the keycode or keycodes required to read data in the particular zone of the second card are stored and any keycode or keycodes received by the coupling means. The first means then transfers such required keycode or keycodes to the reader/writer memory means if the keycode or keycodes received by the coupling means match the respective keycode or keycodes that are required to read the one or more data zones of the memory means of the first card or if no keycodes are required to read such data zones. Thereafter, the first means provides to the input/output means of the second card the read command, a code specifying the particular data zone and the keycode or keycodes for reading data in the particular zone transferred from the memory means of the first card to the reader/writer memory means and transfers any data provided by the input/output means of the second card to the reader/writer memory means.

The two-card reader/writer means also includes second means responsive to the coupling means receiving a command to write to the second card, a code specifying a selected zone in the second card in which data is to be written, data to be written in the selected zone and any keycode or keycodes to be entered in the card for providing to the input/output means of the first card one or more read commands together with a code or codes specifying the data zone or zones of the memory means of the first card where the keycode or keycodes required to write data in the selected zone of the second card are stored and any keycode or keycodes received by the coupling means. The second means then transfers such required keycode or keycodes to the reader/writer memory means if the keycode or keycodes received by the coupling means match the respective keycode or keycodes that are required to read the one or more data zones of the memory means of the first card or, if no keycodes are required to read such data zones. Thereafter, the second means provides to the input/output means of the second card the write command, a code specifying the selected zone, the data to be written in the selected zone and the keycode or keycodes required for writing data in the selected zone transferred from the memory means of the first card to the reader/writer memory.

Thus in accordance with the present invention, by using the IC information card with two-card reader/writer means in the foregoing manner, dissemination of knowledge of the keycodes required to access the data zones of a card is avoided. In the preferred embodiment, the first card includes a data zone storing an identification code unique to that card. The identification code of the first card is read by the reader/writer means and stored in the reader/writer memory following initial insertion of the first card into the reader/writer means. The identification code in the first card is read again

and compared with the identification code stored in the reader/writer memory means prior to each read or write access of the second card. If the identification code which is read prior to an access
5 of the second card fails to match the identification code stored in the reader/writer memory means, access of the second card is prevented.

Further in accordance with the invention, the above-described IC information cards are initialized
10 by a initialization system that includes input means for receiving one of the cards at a time to be initialized and for coupling to the input/output means of the card received thereby and initializer memory means for storing the first keycode, appropriate zone
15 definition data and additional keycode or keycodes. In addition, the initialization system includes first initializer means for writing the zone definition data stored in the initializer memory means to the first region of the memory means of the card received by the
20 input means using the first command, and the first keycode stored in the initializer memory means. Furthermore, the initialization system includes second initializer means for writing the additional keycode or keycodes stored in the initializer memory to the
25 third region of the memory means of the card received by the input means using the second command, and the first keycode stored in the initializer memory means.

The initialization system in accordance with the
30 preferred embodiment of the invention is also used to load the data zones of the IC information card with appropriate data to suit a particular application. This is accomplished by providing the card with second memory means, such as a magnetic stripe, for storing a
35 file identification code and the initialization system with means for reading the second memory, such as a magnetic stripe reader, for obtaining the file identification code of a card received by the input

means of the system. Additionally, the initialization system includes mass storage means for storing a multiplicity of data files each associated with a respective file identification number, each data file
5 having a plurality of data segments corresponding to respective data zones of a card as defined by the zone definition data written into the card by the first initializer means. There is further included third
10 initializer means responsive to the file identification code obtained by the means for reading the second memory means for searching the data files in the mass storage means for the data file associated with that file identification code. The
15 initialization system further includes fourth initializer means for writing the segments of the associated data file into corresponding data zones of memory means of the card received by the input means using the write command and appropriate keycode or
20 keycodes, if any, required for writing data in each corresponding data zone.

There is further provided according to the present invention a method for segmenting the data storage region of the IC card memory into a plurality of segments, each having assignable attributes
25 including an assignable security level and a method for preventing the dissemination of knowledge of the access codes for an IC information card by storing such codes in a control card and using two card read/writer means.

30 Numerous other advantages and objects will appear to those skilled in the art with reference to the following detailed description of the invention, the appended claims and the accompanying drawings.

Detailed Description of the Preferred Embodiments

As shown in Figure 1, the IC card system 100
35 according to the invention comprises an IC card 10, connected via its contacts 24 to corresponding contacts in a reader/writer (R/W) 14. The system also comprises a host computer 16 connected to the

reader/writer 14 by an electrical link 18, which may comprise an RS-232C communications link. The host computer 16 may be an IBM Model XT. As will be described below, the reader/writer 14 has two

- 5 receptacles or ports for receiving up to two IC cards
10 simultaneously. The individual components of the system will now be described in more detail.

IC CARD

- The IC card 10, as shown in Figs. 2A and 2B is preferably the same general size as a conventional magnetic stripe credit card having a size 54 by 86 by 0.76 mm. The IC card has a magnetic stripe 19 and contains a CPU 20 and nonvolatile memory in the form of a PROM or EPROM 22. Alternatively, a storage
15 device such as an EEPROM, i.e. an electrically erasable programmable read only memory, can be used as the storage device. The IC module comprising the CPU 20 and EPROM 22 is enclosed in the card 10 using a between-layers lamination method known to those
20 skilled in the art.

- The IC module is electrically connectable to the reader/writer 14 by means of eight terminals C1 through C8 as shown in Figure 2A. The card size as well as the electrical terminals C1 through C8 are
25 designed to comply with ISO (International Organization for Standardization) standards for IC cards. These standards provide essentially for eight terminals C1 through C8 located and positioned in the arrangement shown in Figure 2A with the dimensions of
30 each terminal being 2.0 by 3.9 mm and edge to edge vertical and horizontal spacings of 0.54 mm and 7.62 mm, respectively. The terminals C1 through C8 are adapted to engage corresponding contacts (not shown) in the reader/writer 14.

- 35 Figure 3 shows in more detail the electrical connections between the terminals C1 through C8, the CPU 20 and the EPROM 22. The CPU may be a model 8049 8-bit microprocessor. The EPROM may be a model 2764 C

with a storage capacity of 64K bits, (i.e. 8K bytes). Electrical connections between the CPU 20 and EPROM 22 include a control bus 26 comprising two lines, an address bus 28 comprising 13 lines, and a data bus 30 comprising 8 lines. Although the particular embodiment shows CPU 20 and EPROM 22 as separate IC chips, it is to be understood that equivalents of those two components may be fabricated on a single IC chip.

10 With respect to the C1 through C8 and with reference to Figure 3, terminal C1 is designated VCC and provides the power (+5 volts) to the CPU and memory. Terminal C2 designated RST is the reset terminal of the CPU. Terminal C3 designated CLK is the clock
15 terminal of the CPU. Terminal C5 designated GND is the ground. Terminal C6 designated VPP is the read/write power terminal of the EPROM (although in some embodiments the single 5 volt power source C1 may accomplish this purpose). Terminal C7 designated I/O
20 is the data input/output terminal for communicating data to and from the reader/writer. Terminals C4 and C8 are not presently used in the exemplary card.

IC CARD MEMORY

A unique feature of the present invention is in
25 providing a user (data) memory area in the EPROM 22 of the card which can be selectively divided into a number of zones, each of which may be selectively accessed (for reading, writing or both) if a key or password code entered into the card by its user
30 permits such access for that particular zone.

The memory of the IC card will be described with reference to Figure 4 which shows the data area of an IC card memory being divided into a plurality of zones, which can be from 1 to 255 in number. Each
35 zone is further divided into a zone allocation area and a number of records from 1 to 255. Each record is further divided into three segments, the first being the segment where the data are stored, the

second being a check byte and the third being a record status byte. The length of the records can be selectively defined by the user to be up to 253 bytes, so that the total size of the data record will be up to 255 bytes, with the check byte (CB) and record status byte (SB) included.

The check byte (CB) is used to detect distorted data in a data record. When a data record is written, the IC card calculates a value using this data by, for example, a check summation using the complement of 2 method, and writes this value into the check byte space. When a record is read, the IC card checks the integrity of the data by performing the same calculation and by comparing the calculated value to the value stored as the check byte. The record status byte (SB) is used for defining record attributes such as data validity and is read or written using the record status byte write-read commands of the IC card program.

20 ZONE DEFINITION

The attributes of each zone are defined by writing a zone definition table into the EPROM of the IC card. The following zone attributes may be defined for each zone:

- 25 1) record length (number of bytes)
- 2) number of records
- 3) security level
- 4) UPDATE/HISTORY.

(a) Record Length

30 The length of data per record is expressed as the number of bytes in the record. The shortest record permitted is one byte, and the longest record permitted is 253 bytes.

(b) Number Of Records

35 The number of records in each zone may range from 1 up to 255.

(c) Security Level

This attribute relates to the access level at the time of writing or reading a record. The IC card normally requires one or two keycodes corresponding to the security level defined for a zone to be entered into the card before reading or writing of data in the zone is permitted. If a keycode stored in the IC card for a particular zone does not match the code entered from an external source (e.g., an IC card reader/writer), data cannot be read or written in that zone. The security control functions of the IC card in accordance with the present invention will be explained in further detail hereinbelow.

(d) UPDATE/HISTORY

This attribute relates to the mode of reading data from a zone. When a zone is defined as "UPDATE", only the most recently written record in the zone is obtained when the zone is read. If a zone is defined as "HISTORY", all records in the zone are obtained in the sequence in which they were written when the zone is read. Whether to define a particular zone as an UPDATE zone or a HISTORY zone depends on the user application.

DATA READ/WRITE

(a) Data Write

Data is written sequentially in a zone in units of records. For example, if in Zone No. N data has been written up to Record No. 1, additional data is written in Record No. 2.

(b) Data read

Data records are read out of only one zone at a time. The method of reading data records depends on whether the zone is defined as UPDATE or HISTORY. If the zone is defined as UPDATE, only the last written record in the zone is read. In the above example, Record No. 2, which was the last to be written, is read if zone No. N is defined as UPDATE. If the zone is defined as HISTORY, all records in the zone are

read in the sequence the records were written. In the above example, data is read from zone No. N in the sequence of Record No. 0, Record No. 1 and Record No. 2 if that zone is defined as HISTORY.

5 (c) Record Status Byte

The configuration of record status byte is shown in Fig. 5. Each of the bits M0 through M7 of the record status byte can be given a special meaning in the data record. The meaning of each bit must be defined in advance by the system application that uses the IC card. The M7 bit is normally used to indicate "record deletion" or "unnecessary record". The record status byte can be written or read by issuing an appropriate command to the IC card.

15 KEY CODES (PASSWORD CODES)

This IC card needs a password code when writing or reading data in the card memory, in order to avoid unauthorized use of the card. The password code is not needed in applications that do not require security as will be described hereinbelow.

There are the following four types of keys or password codes:

- | | | |
|----|--------------------------------|---------|
| | 1) Manufacturer's key (M-key) | 8 bytes |
| | 2) Personalization key (P-key) | 8 bytes |
| 25 | 3) Organization key (O-key) | 8 bytes |
| | 4) PIN | 4 bytes |

(a) Manufacturer's Key (M-Key)

The M-key is defined in the mask program of the microprocessor of the IC card. Therefore, it cannot be read externally by any means. The M-key is a password code consisting of 8 bytes and is specified by the manufacturer prior to the manufacture of the IC. The M-key must be controlled by the manufacturer and the system user and should not be made known to the IC card user. The M-key is used only for internal diagnostic activities within the card. (The system user mentioned here means the party

who issues the initialized cards to user organizations.)

(b) Personalization Key (P-Key)

The P-key is defined in the mask program of the microprocessor of the IC card. Therefore, it cannot be read externally by any means. The P-key is a password code consisting of 8 bytes and can be specified by the system user upon request prior to the manufacture of the IC card. The P-key must be controlled by the system user and should not be made known to the IC card user. The P-key is used on the following occasions:

- (1) to write an organization key;
- (2) to write a PIN key;
- 15 (3) to write zone definition tables; and
- (4) when the system user uses a specific zone for himself.

(c) Organization Key (O-Key)

The O-key is a eight-byte password code that the system user can define after the card is manufactured. When combined with a PIN code, the O-key can provide an additional level of security for the card. Although the O-key can be used in a variety of ways depending on the application, it is normally used as a higher level key than the PIN key. The O-key is stored in the EPROM of the IC card. The O-key may also be used to write the PIN key in the EPROM.

(d) PIN Key

The PIN (Personal Identification Number) key is a four-byte password code that the system user can define after the card is manufactured. As in the case of the O-key, this key can also be used in a variety of ways by the application, but the common use of the PIN key is as a private password code of the IC card user. The PIN key is also stored in the EPROM of the IC card.

SECURITY CONTROL FUNCTION

(a) Security Level

The security level of each zone is defined in the zone definition table. The term "security level" as used herein means the key or combination of keys among those defined (P-key, O-key and PIN) that are required to perform a read or a write operation in a particular zone. Reading and writing operations for a given zone may have different security levels. A 6-bit portion of a zone definition word used to define the security levels for reading and writing in a particular zone and the codes defining the various security levels in accordance with the invention are illustrated in Figure 6.

The different levels of security that are available in the IC card according to the present invention and the key or keys necessary for each security level are summarized in Table A.

TABLE A

20	<u>Security Level</u>	<u>Necessary Key(s)</u>
	0	Access disabled
	1	PIN
	2	O-key
	3	PIN or O-key
25	4	PIN and O-key
	5	P-key
	6	Undefined
	7	No key required

(b) Card Lock

As explained above, the IC card requires a password code or codes as defined by the zone definition table in order to read or write in a zone. If an entered key does not match a required key three times in succession, the card is "locked" or disabled from further use. The "lock" function applies to all

IC card operations (e.g., writing of a Pin or O-key, reading or writing of a zone definition table, reading or writing of a record status byte, etc.) where a key is needed and is not limited only to the reading or
5 writing of a data record.

(c) Card Unlock

Once locked, the card cannot be used. However, it can be made usable by issuing an "UNLOCK" command to the card. Before unlocking a card, it must be
10 carefully determined whether the cause for locking the card was a simple error in memorizing a required key on the part of the card user or an attempt at an unauthorized access of the card. The O-key (or P-key) and the PIN key are both needed to unlock a card. The
15 unlock function can only be performed up to 486 times on a single card.

MEMORY MAP

Figure 7 shows the memory map of an IC card according to the present invention. The card has an
20 EPROM. The 64k-bit memory consists of the following three areas:

- 1) test address;
- 2) system area; and
- 3) user area.

25 (a) Test Address

This is a physical address. Addresses 0, 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048 and 4086 are used for testing at the time of manufacturing or during use of the IC card. During such testing the
30 data of 00H, 11H, 22H, 33H, 44H, 55H, 66H, 77H, 88H, 99H, AAH, BBH, CCH and DDH are written sequentially into the test addresses. If the test data cannot be read or written correctly to each test address, a hardware failure is indicated.

35 (b) System Area

This area is used by the manufacturer of the card and is not in general available to either the system or card user. This area is used to check the card

function, to control the card and to extend the application. The size of this area is 119 bytes.

(c) User Area

This area stores user data and has a size of 8058 bytes. This area is specially defined as "logical address".

Logical address = 0 - 8057 (1F79H) (1)

Unless otherwise specified, the term "address" as used herein means a "logical address".

10 IC CARD FORMATTING OR INITIALIZATION

Prior to reading or writing a data record in the IC card memory, the memory must be formatted (initialized) to correspond to a particular application for the IC card system. The formatting of the IC card memory consists of the following two operations:

- 1) writing of key codes; and
- 2) writing of a zone definition table.

(a) Key Code Write

20 The PIN key (4 bytes) and the O-key (8 bytes) must be written into the IC card memory. If the respective security levels of all zones are defined as "No Key Required", there is no need to write the PIN and O-key into the card. Once written in, the PIN key and the O-key cannot be changed.

(b) Write Zone Definition Tables

As described above, the zone definition attributes are as follows:

- 1) record length;
 - 30 2) number of records;
 - 3) security level (for writing and reading); and
 - 4) UPDATE/HISTORY data record read mode.
- In addition to the above, the following additional zone definition attributes must also be defined:
- 35 5) zone starting address; and
 - 6) number of allocation bytes

A zone definition word for each zone written into the IC card memory is 6-bytes in length containing codes representing the above six attributes.

Figure 8 shows the memory map of an IC card at the time of zone definition. The security management area 705 of the IC card memory is used to store information for detecting unauthorized use of the card. The area 705 also includes three status bits which respectively indicate whether the PIN key and the O-key have been written and whether the zone definition area 706 has been closed. The PIN and O-keys themselves are stored in memory area 705.

The remainder of the security management area 705 (243 bytes) is divided into 486 4-bit nibbles. These nibbles are used one at a time for recording unsuccessful attempts to access the IC card memory. Each time an entered key does not match a required key, the next successive nonzero bit of the current nibble being used to record unsuccessful access attempts is set to zero. When the three lowest order bits of the current nibble are all set to zero, the card is "locked". The card may be "unlocked" by setting the highest order bit of the current nibble to zero. An access in which the entered key matches the required key resets the count. If the current nibble has recorded any unsuccessful access attempts, all bits of the current nibble are set to zero. The unlocking or resetting of the card causes further unsuccessful attempts to be recorded in the next successive nibble.

Figure 8A shows the memory map of an individual zone 707 as indicated on Figure 8. Each zone includes an allocation area 721, which is used to store information as to which records in the zone have been written. The bits within the allocation area 721 are used to keep track of the next available record to be written. The lowest order bit of the first byte of the zone allocation area 721 is set to zero when the

first record 725 of the zone is written. The next lowest order bit in the first byte of the zone allocation area 721 is set to zero when the second record 726 of the zone is written. The process
5 continues as each successive record is written, setting a respective bit for each record, until the maximum number of records, as specified in the zone definition word 703 for that zone, is written. When the last allocated record 727 is written, no further
10 records may be written to the zone 707, although the data in the zone may still be read. In the present exemplary embodiment the zone allocation area for each zone is located within the zone itself. However, in some instances it may be desirable to locate the zone
15 allocation areas for all the zones together in a separate area of the card memory.

The check byte (CB) 723 has already been discussed in connection with Fig. 4. The status byte (SB) 724 has already been discussed in connection with
20 Figures 4 and 5.

Up to 255 zones may be defined in the IC card memory. Since the starting address of a zone is stored in the zone definition word, there may be unused memory space between the end of the zone
25 definition table area and the start of the first zone. A similar unused memory space may exist between two adjacent zones.

(c) Zone size

The size of Zone No. "n" (expressed as L(n)-
30 number of bytes) is calculated using the following formula:

$$L(n) = m(n) \times (l(n) + 2) + m(n)/8 \quad (2)$$

where l(n) is the record length in number of bytes and m(n) is the number of records. Decimal fractions are
35 rounded to the next higher integer.

(d) Zone Address Calculation

Assuming that the number of zones to define is M, that the same address is not used for two or more

places and that no unused memory space exists, the start address $S(N)$ of the N -th zone is calculated as follows:

$$5 \quad S(N) = \sum_{n=1}^{N-1} L(n) + 6M + 256 \quad (3)$$

The end address $E(N)$ of the N -th zone is calculated as follows:

$$10 \quad E(N) = \sum_{n=1}^N L(n) + 6M + 255 \quad (4)$$

From the above formulae, the last address $E(M)$ of the IC card memory is calculated as follows:

$$15 \quad E(M) = \sum_{n=1}^N L(n) + 6M + 255 \quad (5)$$

However, because of the limit on the IC card memory area the last address $E(M)$ is as follows:

$$E(M) \leq 8057 \quad (6)$$

20 Because of the limit of available RAM buffer space, the product of record length and number of records in a zone may not exceed 2048.

$$l(n) \times m(n) \leq 2048 \text{ (800H)} \quad (7)$$

IC CARD OPERATION

25 Figure 9 is a flow diagram of the IC card operation. In accordance with this flow chart, the IC card first receives a command from the reader/writer at 801. The IC card then does a check at 803 to determine whether the command is supported by the
30 card. If the command is not valid, an error code indicating such is produced at 804 and processing stops. However, if the command is valid, it is

executed at 805, and the output as a result of command execution is provided at 806.

COMMAND DESCRIPTION

The IC card uses 15 commands which are classified into 8 different groups, namely, IC card hardware test, formatting, key write, zone read/write, records remaining to be written in a zone, record status management, and card program version information read. It should be understood that some commands require particular keys and parameters for their execution. The IC card commands in accordance with the present invention are listed in Table B herein.

RESULT OF EXECUTIONS BY THE IC CARD (RESPONSES)

The IC card informs the reader/writer of the result of the execution of a command. If the command includes a read command, the data obtained through execution of the read command are included in the response provided to the reader/writer. The response indicating command execution by the IC card can take the form of one or more return codes.

READER/WRITER COMPONENT

The reader/writer 14 which is connected to the host computer 16 via a RS-232C communication link 18 and which accepts one or two IC cards will now be described. Figure 10 is a block diagram of a reader/writer 14 showing two ports numbered 1 and 2 (914 and 915) for receiving the IC information cards described above. The respective reader/writer ports

are connected to card interfaces (I/F) 902 and 901 which are in turn connected via a data/address bus 903 to other components in the reader/writer. Also connected to the card interfaces 902 and 901 are
5 respective buzzers or sound transducers 904 and 905, each of which may produce a different frequency, e.g. 600 Hertz and 2400 Hertz. A RAM memory 906 of 8K bytes, ROM memories 907 and 907A having a total of 16K bytes, and a CPU 908 in the form of a Z80A
10 microprocessor are also connected to the data/address bus 903. The RS-232C interface 909 is also connected to the data/address bus 903. The reader/writer 14 is provided with a power supply 910 which receives 90 to 130 volts AC through a noise filter 911 and which
15 supplies DC voltages of 5 volts, +12 volts and - 12 volts.

As part of the reader/writer ports 914 and 915, card transports are provided for transporting the cards into and out of the reader/writer ports. Such
20 transports are commercially available from various manufacturers, such as the Toppan Moore Company, Ltd. of Tokyo, Japan. An electrical schematic diagram of the interface for such a card transport is shown in Figure 11. In the lower portion of the figure, the
25 electrical connections provided to the terminals of the IC card are indicated.

When an IC card is inserted into one of the read/write ports, a solenoid is activated and the

respective card is held in place within the reader/writer 14. At this time, the corresponding card insertion state LED 912 or 913 as shown in Figure 10 is illuminated. When transactions involving the card are completed, the inserted card can be removed by pressing the card eject button 916 or 917 for the port in which the card is inserted. However, if the card eject button is pressed during IC card operation, i.e., while IC card operation indicator LED 918 or 919 is lit, the card eject button will be inoperative. The card may also be ejected by a command issued by the host computer as will be described below. When the card is ejected, the card insertion state LED 912 or 913 is extinguished.

15 A more detailed schematic diagram of the reader/writer in accordance with the invention is shown in Figures 12 and 13. Figure 12 shows on the left the Z80A CPU unit 908 being connected on the upper left to a clock which drives one of its inputs. A reset circuit is also provided on the left of this figure, as well as connections to the power LED and the connection socket for the power supply. Shown on the upper right in Figure 12 are the ROMs 907 and 907A and the RAM 906, which are connected to the Z80A CPU 908 by an address bus in the upper part of the figure and a data bus in the central part of the figure. A baud rate selection dip switch arrangement is shown in the bottom center portion of the figure, which also

provides square wave outputs to drive the respective buzzers. Also shown in the bottom portion of this figure is the RS-232C interface which is connected to the baud rate selection chip and to the cable connector to the RS-232C interface.

Referring to Figure 13, the card interface units 901 and 902 are shown respectively in the right and left hand portions of the figure. Each of the interface units is connected to the data bus in the upper portion of the figure, and are connected to the various solenoid coils in the respective transport units of the reader/writer ports 914 and 915 via connection strips CN2 and CN3, respectively. The buzzer 905 for the card I/F1 is connectable to terminals a and b in the bottom right portion of the figure, and the buzzer 904 for card I/F2 is connectable to terminals c and d in the bottom center of the figure.

The reader/writer memory map is illustrated in Figure 14. This memory map shows the BIOS program area resident in a portion of the 8K byte area of ROM1 907, and the buffer for the BIOS present in a portion of the 8K byte area of RAM 906.

IC CARD SECURITY SYSTEM SOFTWARE

Figure 15 shows the configuration of the software provided for the present IC card system in simple block form. As shown in this figure, the host computer 16 contains the host application program and the input/output (I/O) handler. The I/O handler of

the host communicates with the reader/writer 14 through the BIOS program of the reader/writer. The reader/writer also has an application program. Communication with the IC card 10 is made through the BIOS program of the reader/writer as shown. The IC card 10 also has its own card program resident in its microprocessor memory.

The host application program is prepared according to the particular business requirements of the IC card system user. The I/O handler of the host provides the basic input/output routine for communication between the host computer and reader/writer. The BIOS program is the input/output handler for the IC card reader/writer and can perform input/output operations via the RS-232C link to the host computer, input/output operations to and from the IC cards, and other functions. Typical other functions include turning on and turning off of the internal buzzers 904 and 905 of the reader/writer, and checking whether a card is inserted or not inserted. The application program of the reader/writer is prepared according to the requirements of the system. The card program which is built into the CPU of the IC card during chip fabrication controls the configuration and access of the IC card and the card memory, as described above.

The reader/writer is designed to facilitate the host computer in accessing the data stored in the IC

card in order to fully utilize the IC card functions. Commands issued by the host computer can be divided roughly into the following command types:

reader/writer control commands, data record control
5 commands, IC card issue commands (IC card format command), and security related commands.

The reader/writer application program implements the reader/writer BIOS commands, which are listed in
TABLE B herein. It should be understood that the host
10 computer and the IC card reader/writer can be connected over a telecommunication link via a modem/acoustic coupler.

The reader/writer application program in the preferred embodiment incorporates a security plan which
15 uses one of the two cards as the control card and the second as the application or user card. This approach increases the overall security of the system by avoiding the dissemination of knowledge of the keys required to access the various data zones of the IC
20 card memory. For example, the O-key need not be known to any person, since it can be stored in the control card. Therefore, that key is not readily available to someone who wishes to make an unauthorized access attempt in the user card. Additionally, the two card
25 approach eliminates the need for the entry of the access keys and other information by the system user.

The reader/writer application program illustrated in Figure 40, operates as follows: After

initialization 4001, a unique field (serial number) is read from the control card and stored in the reader/writer for later comparisons, process 4003. Various keys may then be read from protected zones

5 within the control card, e.g., O-key, PIN key and any additional user defined keys, using processes 4004 through 4014, and stored within the reader/writer for later use in accessing the application or user card. It is noted that these keys may also be loaded into

10 the reader/writer memory from the host computer. The commands from the host computer specify what kind(s) of key(s) are required for the specific operation. The reader/writer application program interprets the commands and by using the previously stored keys

15 issues the BIOS commands necessary to accomplish the specified operation. The additional security features of the reader/writer application program come into play at this point. Prior to issuing a command to the user card which requires one or more keys, the

20 reader/writer application program checks the control card serial number, at 4009 to make sure that the control card has not been changed. If it has been changed, the control card serial number and the applicable keys in the reader/writer are set to zero,

25 and an error message is returned to the host computer. Under such conditions, the command to the user card is not carried out. The commands defined by the

reader/writer application program are listed in Table E.

As shown in Figure 14, the user's program area occupies memory locations 1000H to 1FFFH, or from 5 1000H to 3FFFFH if optional ROM2 is used. The memory location in the RAM area at addresses E000H to E0FFH, i.e., 256 bytes, is used as a data buffer and as a stack for the BIOS program, leaving the RAM area from E100H to FFFFH as user memory.

10 ISSUE SYSTEM COMPONENTS AND OPERATION

The IC cards can be formatted (initialized) and personalized in a number of ways. The terms "formatting" and "initialization" both refer to the writing of the O-key, the zone definition table and, 15 optionally, the PIN key in the IC card memory. The term "personalization" refers to the writing of appropriate data records in the data zones of the IC card memory.

One aspect of the present invention is to format 20 and personalize a large number of IC cards for a particular application on a mass production basis. To accomplish this, an arrangement as shown in Fig. 16 is used which comprises an initializer (I/Z) 50 used in conjunction with a host computer 16. The host 25 computer in the preferred embodiment is an IBM-XT having a CRT, a keyboard, a printer, a 10 MB hard disk, and a one or more double floppy diskette drives. The initializer 50 and the host computer 16 are

connected to each other by a RS-232C communications link.

In accordance with the personalization process, the respective data files to be loaded into the IC
5 cards are stored on the hard disk or floppy diskette or some other mass storage medium and are accessed by way of a personal code for each personal data file stored in the mass storage medium. Each IC card to be
10 personalized is provided with a magnetic stripe in accordance with the conventional format and is magnetically encoded with a personal code for addressing a corresponding personal data file in the mass storage medium. The magnetic encoding of the magnetic stripe is carried out using conventional
15 techniques preferably on the second track of the stripe in accordance with the ABA standard or JIS type I, or the first track in accordance with JIS type II.

The initializer 50 has an input slot or an input
20 hopper for accepting cards and a card handler for moving each card automatically through a magnetic stripe reader to electrical contacts in the initializer which make electrical contact to respective IC card contacts C1-C8. Each card is first
25 initialized by writing the O-key, the zone definition table and, optionally, the PIN key in the card memory. Such initialization information and the P-key, which is required before the initialization information can

be written into the card memory, have been previously entered into the initializer and are stored in the initializer memory. The initialization information and the P-key are advantageously entered into the
5 initializer by means of a master card, as will be described in further detail herein below.

Following initialization, if the card in the initializer is to be personalized, the personal code on the magnetic stripe is read and transferred to the
10 host computer. In response to receiving the personal code of the card, the computer addresses the corresponding personal data file in the mass storage medium and personalizes the card by writing the data in the file in previously defined zones of the IC card
15 memory. The initialized and personalized cards are then ejected.

In order to operate such a system, master cards 52, one or more IC cards 10, and several data files must be prepared. There are four types of master
20 cards 52, one for each operation of the initializer. All master cards are previously written with information necessary for the respective operation according to a predetermined format. The information written on the master cards includes a different
25 identification code for each operation and a batch number which is necessary for issue control. Figure 17 is a memory map of a master card 52.

The different operations of the IC card initializer include formatting, (initialization), personalization, unlocking, and formatting (initialization) with personalization.

5 The files necessary for formatting and personalization include a Z.D.T. (zone definition table) data file and an index file. The Z.D.T. file is used for formatting or for formatting with personalization. If the Z.D.T. data is written in the
10 master card, the Z.D.T. file need not be stored in the memory associated with the host computer.

The index file is used for personalization or for formatting with personalization. The file contains the record length, the field configuration, and field
15 number of the personal data file, the field number being used for the search. Also used for personalization or for formatting with personalization is a zone and field correspondence file in which the correspondence between the zone numbers in the card
20 memory and the fields of the personal data file are defined. Lastly, a personal data file is used for personalization or for formatting and personalization. This file is prepared by the user of the system and consists of fixed length records not including a
25 header and contains a field for record search.

The host computer has a main program to carry out initialization (formatting), personalization, unlocking or both initialization (formatting) and

personalization of an IC card. The Z.D.T. data file, the personal data files, the index file and the zone and field correspondence file must all be created before an IC card is initialized and personalized by
5 the main program. The main program also needs a master card on which the required data is written in a certain format.

MAIN PROGRAM

Figure 18 is a flow chart showing the pre-
10 operation portion of the main program. The program first asks the user whether the communication parameters of baud rate, parity, stop bit and byte length should be set to their default values of 9600, none, 2 and 8, respectively. If not, the user then is
15 requested to input other values for these parameters. The pass word is then requested, and if the entered password is satisfactory, the date and time are displayed for verification by the user. If the date and time are not correct, the user should input "n"
20 which causes the program to return the system to DOS to allow the correct date and time to be entered. Once this has been done and the program reinitiated, if needed, the system completes the pre-operation. Thereafter the screen displays five menu items of
25 format, personalization, unlock, format with personalization, and end. The user selects which one of the five menu items he desires. The first four menu items are now described.

FORMATTING (INITIALIZATION)

Figure 19 shows the flow chart for the formatting program. When this menu item is selected, the master card is inserted by the user, and the PIN number for the master card is requested and entered by the user. If the inserted master card contains the ZDT data and the O-key (or a corresponding key for a different embodiment) such data and key are automatically read, and the master card is ejected. The program then asks the user to enter the number of cards which are to be formatted. If the inserted master card does not contain the ZDT data, the system reads the ZDT data file from the memory associated with the host computer. The file contents are then displayed and checked by the user. If the inserted master card does not contain the O-key data, this data is entered from the keyboard by the user. The master card processing is then complete, and the IC cards to be formatted are then inserted into the initializer. Each time a card is formatted, the user is asked whether or not the formatting should continue for the remaining cards or whether the formatting should be terminated. When the desired number of cards have been formatted, the main program returns to the menu.

25 PERSONALIZATION

Figure 20 shows the flow diagram for the personalization program. In accordance with this program, master card insertion is requested, and if the

inserted master card is found to be correct, the entry of the PIN number for the master card is requested from the user. If the master card contains the O-key, the system automatically reads the key, and the master
5 card is ejected. However, if the master card does not contain the O-key data, the user must enter this data via the keyboard. The system then reads the three files necessary for personalization, namely: the index file; the personal data file; and the zone and field
10 correspondence file. After the system has read the contents of all the necessary files, it requests the insertion of cards to personalize. The cards inserted into the initializer at this point must have been previously formatted and have the appropriate magnetic
15 data encoded on their magnetic stripes in order to allow the host computer to find the proper personal data file in the mass storage medium.

The IC cards are then fed, one at a time, into the initializer. The initializer reads the magnetic
20 stripe on each card to find the personal code and obtains the personal data file corresponding to that personal code from the mass storage medium and writes the personal data from the file into the IC card memory. At this time the PIN key may also be written
25 into the IC card. The PIN number may also be written into the IC card at a later time by the system user. After each card is personalized, the system requests whether further personalization of the remaining cards

should continue. Once all of the cards have been personalized or upon early termination of the personalization process, the main program returns to the menu.

5 UNLOCK PROCESS

Figure 21 shows the flow chart procedure for the unlock process. According to this process, the program asks the user to insert the master card and to input the PIN key for the master card. The O-key is
10 then entered by the user from the keyboard of the host computer if the inserted master card does not contain this key. The master card is then removed and the IC cards to be unlocked are then inserted. The individual PIN keys associated with each card are then
15 entered, and the system checks to see whether these PIN numbers are correct. After each card is unlocked (or if unlock is refused because of an improper PIN number), the card is ejected and the user has the option of continuing with further unlocking of the
20 other cards or returning to the menu.

FORMATING AND PERSONALIZATION IN COMBINATION

Figure 22 shows the flow chart for the formatting (initialization) with personalization in combination. This flow chart is essentially a combination of the
25 individual steps from the formatting and personalization flow charts of Figures 19 and 20.

OUTPUT FILE

An output file called XREPORT (wherein X may be replaced by F, P, U or C depending upon the type of operation carried out by the initializer, i.e.,
5 formatting, personalization, unlocking or formatting and personalization combined) is prepared during initializer operation. All errors made during the operation are recorded in a file called XERROR, wherein X may be replaced by F, P, U or C. All file
10 contents can be checked using conventional file handling means.

INITIALIZER COMMUNICATIONS SPECIFICATION

All communications between the host computer and the initializer are carried in string format
15 comprising two bytes indicating string length, one byte indicating the type of string, bytes of data and one final byte indicating the checksum. The string length is a two byte field indicating the length of the entire string excluding the checksum byte at the
20 end of the string. (The order of the field is the least significant byte first and the most significant byte last.) There are four types of strings, namely, a command string (designated by 01), a data string (02) and information string (03) and a control string
25 (04). The data can be any number of bytes needed corresponding to a string type. The checksum is the sum of all string data just before the checksum and is provided in two's complement format.

The command string format is essentially the same general format as indicated above, except that the data comprises a command code and parameters. The format for the data string is also essentially the same as described above, except that the data includes a field indicating the number of data elements and another field indicating the data length in bytes. The format for the information string is essentially the same as that described above, except that the string length is fixed at 5, and the data includes error type and error detail examples. The format for the control string is also generally the same as that described above, except that the string length is fixed at 4 and the control code is one of three types, namely, 01H indicating ACK, 02H indicating NAK, 03H indicating EOT.

PROGRAM LISTING AND COMMAND CODES

A print listing for the reader/writer basic input/output system (BIOS) in accordance with the invention is included in Appendix I. A listing of the BIOS commands is provided in Table C herein. Table D herein lists these commands and shows the information transferred between the reader/writer and IC card during command execution, as well as the string format.

Figures 23 through 39 illustrate the command protocols between the reader/writer and IC card, showing the direction and sequence of command, parameters,

return and error codes between the reader/writer and IC card. The commands illustrated in these figures correspond generally to many of the BIOS commands listed on Table C herein.

5 A print listing of the reader/writer application program, in accordance with the present invention, is also included in Appendix I. The commands used in the reader/writer application program are shown in Table E herein, which also illustrates the protocol used with
10 the commands.

 Figures 41 through 91B are flow charts of the IC card program, in accordance with the present invention. A print listing of the IC card program, in accordance with the invention, is included in Appendix
15 I.

 Figures 92 through 108B illustrate the command protocol between the host computer and initializer (I/Z) during the initialization process.

 While a particular embodiment of an IC card
20 security system has been shown and described, numerous variations and modifications will readily occur to those skilled in the art. The invention is not intended to be limited to the embodiment illustrated and described but is merely illustrative of the
25 application of the principles of the invention, whose scope is pointed out in the appended claims.

TABLE B

COMMAND		NEMONIC	FUNCTION
CODE (hex)			
5	21H	PINWR	PIN Code WRITE
	23H	OKEYWR	Organization KEY WRITE
	25H	WRZDT	WRITE Zone Definition Table
	26H	CLZDA	CLOSE Zone Definition Table Area
	24H	RDZDT	READ Zone Definition Table
10	10H	RDZONE	READ RECORDS In a Zone
	11H	WRZN	WRITE RECORD onto a Zone
	13H	WRZNVV	WRITE RECORD onto a Zone with Verify
	15H	STWR	Record Status Byte Mark
	14H	STRD	Record Status Byte Read a Zone
15	27H	UNLOCK	UNLOCK the locked Card
	28H	REMAIN	READ Number of Remaining Records
	30H	MTEST	CARD TEST AT MANUFACTURING
	31H	RTEST	CARD READ TEST
	42H	RDMPD	READ MASK PROGRAM DATA (NAME)

TABLE C

BIOS COMMAND LIST
<BIHWT11C>

5	COMMAND CODE (hex)	NEMONIC	FUNCTION
	01H	SELCR1	Select Card reader #1
	02H	SELCR2	Select Card reader #2
	03H	BZON	Buzzer on
	04H	BZOFF	Buzzer off
10	05H	SDIN	RS-232C Data input
	06H	SDOUT	RS-232C Data output
	07H	CDINCK	Card in check
	08H	INIT	Initialize IC card reader/writer
	09H	CEJCT	Card eject
15	10H	RDZN	Read a zone
	11H	WRZN	Write a zone
	13H	WRZNV	Write a zone with verify
	14H	STRD	Read record status byte
	15H	STWR	Write record status byte
20	21H	PINWR	Write Pin code
	23H	OKEYWR	Organization key write
	24H	RDZDT	Read Zone Definition Table
	25H	WRZDT	Write Zone Definition Table
	26H	CLZDA	Close Zone Definition Table Area
25	27H	UNLOCK	security lock cancel
	28H	REMAIN	read remaining number of records
	30H	MTEST	Card test at manufacturing
	31H	RTEST	Card read test (test at using)
	42H	RDMPD	Read mask program data

30 note: command code and another parameter should be set to A-register and proper registers before BIOS call.

GENERAL INFORMATION:

15 All commands, and parameters sent to the card, if any for the particular command, are terminated by an ASCII Carriage Return - Line Feed pair of characters. Additionally, all data transmissions from the Reader/Writer are also terminated by an ASCII Carriage Return - Line Feed pair of characters.

20 All commands which require a key to operate (unless there is a choice of keys available) require that the key be previously set for the R/W - either from the host or from the control card. The E (Either) option requires the key type and key be entered from the host program.

TABLE F

Command codes are:

	00H:	NOP
	01H:	Card in
5	02H:	Card out
	03H:	Write magnetic data
	04H:	Read magnetic data
	05H:	Contactator down

	0DH:	On each output device
	0EH:	Off each output device
	0FH:	Transmit data
	10H:	Write PIN

Claims

1. An IC information card comprising:
input/output means in the card for receiving
at least data, commands and keycodes and for
5 providing at least data;
nonvolatile read/write memory means within
the card, the memory means having a multiplicity
of addressable bit storage locations;
first means within the card responsive to a
10 first command, zone definition data and an
entered keycode received by the input/output
means for comparing the entered keycode with a
first keycode stored in the card and for writing
the zone definition data in a first region of the
15 memory means only if the received keycode matches
the first keycode, the zone definition data
comprising one or more zone definition words each
corresponding to a respective data zone in a
second region of the memory means, each zone
20 definition word specifying at least the starting
address of the corresponding data zone and the
size of the corresponding data zone.
2. An IC information card according to claim 1,
wherein the card further comprises second means
25 within the card responsive to a second command,
keycode data comprising one or more additional
keycodes and an entered keycode received by the
input/output means for comparing the entered
keycode with the first keycode and for writing
30 the keycode data in a third region of the memory
means only if the entered keycode matches the
first keycode, and wherein each zone definition
word further specifies either no keycode or one
or more of the first keycode and the additional
35 keycode or keycodes as being required to be
received by the input/output means in order to

5 read data from the corresponding zone and either
no keycode or one or more of the first keycode
and the additional keycode or keycodes as
being required to be received by the input/output
means in order to write data in the corresponding
data zone.

3. An IC information card according to claim 2,
wherein the card further comprises third means
within the card responsive to the input/output
10 means receiving a read command, a code specifying
a particular one of the data zones from which
data is to be read and any entered keycode or
keycodes, for comparing any entered keycode or
keycodes with any keycode or keycodes specified
15 as being required to read data in the particular
data zone and for providing data from the
particular zone to the input/output means if the
entered keycode or keycodes match the keycode or
keycodes specified as being required to read data
20 from the particular data zone or if no keycode is
specified as being required to read data from the
particular data zone, and wherein the card
further comprises fourth means within the card
responsive to the input/output means receiving a
25 write command, a code specifying a selected one
of the data zones in which data is to be written,
data to be written in the selected zone and any
entered keycode or keycodes, for comparing any
entered keycode or keycodes with any keycode or
30 keycodes specified as being required to write
data in the selected data zone and for writing
the received data in the selected data zone if
the entered keycode or keycodes match the keycode
or keycodes specified as being required to write
35 data in the selected data zone or if no keycode
is specified as being required to write data in
the selected data zone.

4. An IC information card according to claim 3,
wherein data is stored in each data zone as
successively located data records and each zone
definition word further specifies the maximum
5 number of data records that can be stored in the
corresponding zone, the length of the data in
each data record in the corresponding zone and a
zone allocation area in the memory means for
storing data indicative of the location of the
10 next data record to be stored in the
corresponding zone.
5. An IC information card according to claim 4,
wherein the zone allocation area is located in
the corresponding zone and contains one or more
15 successively ordered bit positions each
associated with a respective data record position
in the zone, each bit position of the zone allo-
cation area containing a first or a second binary
state depending upon whether or not the data
20 record position associated with that bit position
contains a data record, respectively, and wherein
the fourth means is further responsive to the
contents of the zone allocation area of the
selected zone for writing a data record in the
25 selected zone in the data record position therein
that is associated with the lowest order bit
position of the zone allocation area therein con-
taining the second binary state and for writing a
first binary state in that lowest order bit
30 position containing the second binary state.
6. An IC information card according to claim 4,
wherein each data record stored in a data zone
includes a checksum byte and a second status byte
indicative of the validity of the data in the
35 data record.

7. An IC information card according to claim 4,
wherein each zone definition word further
specifies whether the data provided to the
input/output means by the third means in response
to a read command and a code specifying data to
be read from the corresponding zone is only the
last data record to be written in the
corresponding zone or all data records that are
stored in the corresponding zone in the order in
which such data records are written in the
corresponding zone.
8. An IC information card according to claim 3,
wherein the third region of the memory means
further contains a plurality of successively
ordered lock status words, including a first and
a last lock status word, each lock status word
having a predetermined number of successively
ordered bit positions, including a first and a
last bit position, each bit position of each lock
status word being initially in a second binary
state, and wherein the card further comprises
fifth means within the card responsive to a
failure of an entered keycode to match a keycode
stored in the card, as a result of a keycode
comparison made by the first, second, third or
fourth means, for writing a first binary state in
the lowest order bit position that is in the
second binary state of the lowest order lock
status word in which the highest order bit
position is in the second binary state, the fifth
means being responsive to a match of an entered
keycode with a keycode stored in the card
occurring directly after a failure of an entered
keycode to match a keycode stored in the card, as
a result of a comparison made by the first,
second, third or fourth means, for writing a
first binary state in the highest order bit

- position of the lock status word in which a first binary state was written by the fifth means in response to the directly preceding failure of an entered keycode to match a keycode stored in the card, and wherein the card further comprises sixth means within the card responsive to a lock status word having all but its highest order bit position in the first binary state for placing the card in a locked state in which at least reading and writing access to the first and second regions of the memory means are prevented, and seventh means within the card responsive to an unlock command and one or more entered keycodes for comparing the entered keycode or keycodes with preselected keycode or keycodes stored in the card and for writing a first binary state in the highest order bit position of the lock status word having all but the highest order bit position in the first binary state to release the card from the locked state, if the entered keycode or keycodes match the preselected keycode or keycodes.
9. An IC information card according to claim 8, wherein the first, second, third, fourth, fifth, sixth and seventh means are included in an appropriately programmed microprocessor operatively coupled to the input/output means and the memory means includes a programmable read-only memory operatively coupled to the microprocessor.
10. An IC information card system comprising:
a first and second IC information card each having:
(a) input/output means in the card for receiving at least data, commands and keycodes and for providing at least data,

(b) means storing a first keycode,

(c) nonvolatile memory means within the card having a first region for storing one or more keycodes and a second region segmented into a plurality of data zones, each one of the data zones being defined to require either no keycode or a specified one or more of the first keycode and the keycode or keycodes stored in the first region to be entered into the card in order to read data in that data zone and to require either no keycode or a specified one or more of the first keycode and the keycode or keycodes stored in the first region to be entered into the card in order to write data in that data zone,

(d) first means within the card responsive to the input/output means receiving a read command, a code specifying a particular one of the data zones in which data is to be read and any entered keycode or keycodes, for comparing any entered keycode or keycodes with any keycode or keycodes specified as being required to read data in the particular data zone and for providing data from the particular zone to the input/output means if the entered keycode or keycodes match the keycode or keycodes specified as being required to read data in the particular data zone or if no keycode is specified as being required to read data from the particular data zone, and

(e) second means within the card responsive to the input/output means receiving a write command, a code specifying a selected one of the data zones in which data is to be written, data to be written into the selected zone and any entered keycode or keycodes, for comparing any entered keycode or keycodes with any keycode or keycodes specified as being required to write data in the selected data zone and for writing

the received data in the selected zone if the entered keycode or keycodes match the keycode or keycodes specified as being required to write data in the selected data zone or if no keycode is specified as being required to write data in the selected zone, wherein the memory means of the first card includes one or more data zones each storing a respective one or a combination of the first keycode and the keycode or keycodes stored in the first region of the memory means of the second card; and

IC card reader/writer means having:

- (a) a first and a second port for receiving the first and second cards, respectively, and for coupling to the input/output means thereof,
- (b) coupling means for receiving at least commands, data and keycodes and for providing at least data,
- (c) reader/writer memory means,
- (d) first means responsive to the coupling means receiving a command to read the second card, a code specifying a particular zone in the second card in which data is to be read and any keycode or keycodes to be entered in the first card, for providing to the input/output means of the first card one or more read commands together with a code or codes specifying the data zone or zones of the memory means of the first card where the keycode or keycodes required to read data in the particular zone of the second card are stored and any keycode or keycodes received by the coupling means, for transferring such required keycode or keycodes to the reader/writer memory means if the keycode or keycodes received by the coupling means match the

5 respective keycode or keycodes that are
 required to read the one or more data zones
 of the memory means of the first card or if
 no keycodes are required to read such data
10 zones, for providing to the input/output
 means of the second card the read command, a
 code specifying the particular data zone and
 the keycode or keycodes for reading data in
 the particular zone transferred from the
15 memory means of the first card to the
 reader/writer memory means, and for trans-
 ferring any data provided by the
 input/output means of the second card to the
 reader/writer memory means, and
20 (e) second means responsive to the
 coupling means receiving a command to write
 to the second card, a code specifying a
 selected zone in the second card in which
 data is to be written; data to be written in
25 the selected zone and any keycode or
 keycodes to be entered in the first card for
 providing to the input/output means of the
 first card one or more read commands
 together with a code or codes specifying the
30 data zone or zones of the memory means of
 the first card where the keycode or keycodes
 required to write data in the selected zone
 of the second card are stored and any
 keycode or keycodes received by the coupling
35 means, for transferring such required
 keycode or keycodes to the reader/writer
 memory means if the keycode or keycodes
 received by the coupling means match the
 respective keycode or keycodes that are
 required to read the one or more data zones
 of the memory means of the first card or if
 no keycodes are required to read such data
 zones, and for providing to the input/output

- means of the second card the write command,
a code specifying the selected zone, the
data to be written in the selected zone and
the keycode or keycodes required for
5 writing data in the selected zone
transferred from the memory means of the
first card to the reader/writer memory.
11. IC information card system according to claim 10,
wherein the memory means of the first card
10 includes a first data zone containing an
identification code for the card and wherein the
reader/writer means further comprises third means
for reading the first zone of the memory means of
the first card following initial coupling of the
15 first card to the reader/writer means and
transferring the identification code therein to
the reader/writer memory means and for reading
the first zone of the memory means of the first
card each time the coupling means receives a
20 command to read the second card or command to
write to the second card and comparing the con-
tents read therein with the identification code
stored in the reader/writer memory means, the
third means preventing at least reading and
25 writing of the memory means of the second card if
the contents of the first data zone of the memory
means of the first card fails to match the
identification code stored in the reader/writer
memory means.
- 30 12. An initialization system for IC information cards
each including first means within the card
responsive to a first command, zone definition
data and an entered keycode received by the
input/output means for comparing the entered
35 keycode with a first keycode stored in the card
for writing the zone definition data in a first

region of the memory means only if the received
keycode matches the first keycode, the zone
definition data comprising one or more zone
definition words each corresponding to a
5 respective data zone in a second region of the
memory means, each zone definition word
specifying at least the starting address of the
corresponding data zone and the size of the
corresponding data zone, and second means within
10 the card responsive to a second command, keycode
data comprising one or more additional keycodes
and an entered keycode received by the
input/output means for comparing the entered
keycode with the first keycode and for writing
15 the keycode data in a third region of the memory
means only if the entered keycode matches the
first keycode, and wherein each zone definition
word further specifies that either no keycode or
one or more of the first keycode and the
20 additional keycode or keycodes are required to be
received by the input/output means in order to
read data from the corresponding zone and either
no keycode or one or more of the first keycode
and the additional keycode or keycodes are
25 required to be received by the input/output means
in order to write data in the corresponding data
zone, the system comprising:

 input means for receiving one of the
cards at a time to be initialized and for
30 coupling to the input/output means of the card
received thereby;

 initializer memory means for storing the
first keycode, appropriate zone definition data
and additional keycode or keycodes;

35 first initializer means for writing the zone
definition data stored in the initializer memory
means to the first region of the memory means of
the card received by the input means using the

first command, and the first keycode stored in the initializer memory means; and

5 second initializer means for writing the additional keycode or keycodes stored in the initializer memory to the third region of the memory means of the card received by the input means using the second command, and the first keycode stored in the initializer memory means.

10 13. An IC information card initializer system according to claim 12, wherein the first keycode, the zone definition data and the additional keycodes are stored in a master card which is received by the input means before receiving the first one of the cards to be initialized and the
15 system further comprises third initializer means for transferring the first keycode, the zone definition data and the additional keycode or keycodes from the master card to the initializer memory means.

20 14. An IC information card initialization system according to claim 12, wherein the system further comprises automatic feeder means for receiving a multiplicity of the cards to be initialized and for feeding the cards one at a time to the input
25 means and automatic receiving means for receiving a card after the zone definition data and the additional keycode or keycodes have been written into the memory means thereof.

30 15. An IC information card initialization system according to claim 12, wherein the card further includes third means within the card responsive to a write command, a code specifying a selected one of the data zones in which data is to be written, data to be written in the selected zone
35 and any entered keycode or keycodes received by

the input/output means for comparing any entered
keycode or keycodes with any keycode or keycodes
specified as being required to write data in the
selected data zone and for writing the received
5 data in the selected data zone if the entered
keycode or keycodes match the keycode or keycodes
specified as being required to write data in the
selected data zone or if no keycode is specified
as being required to write data in the selected
10 data zone, and second memory means for storing a
file identification code, and wherein the system
further comprises:

means for reading the second memory means
for obtaining the file identification code of a
15 card received by the input means;

mass storage means for storing a
multiplicity of data files each associated with a
respective file identification number, each data
file having a plurality of data segments
20 corresponding to respective data zones of a card
as defined by the zone definition data written
into the card by the first initializer means;

third initializer means responsive to the
file identification code obtained by the means
25 for reading the second memory means for searching
the data files in the mass storage means for the
data file associated with that file identi-
fication code; and

fourth initializer means for writing the
30 segments of the associated data file into
corresponding data zones of memory means of the
card received by the input means using the write
command and appropriate keycode or keycodes, if
any, required for writing data in each
35 corresponding data zone.

16. An IC information card initialization system
according to claim 15 wherein the second memory

means of the card is a magnetic stripe on the card and the means for reading the second memory means is a magnetic stripe reader.

17. In an IC information card containing a non-volatile memory means having a multiplicity of addressable bit storage locations, a method for segmenting a data storage region of the memory means into a plurality of data zones, each having assignable attributes including an assignable security access level, the method comprising the steps of:
- defining first, second and third regions in the memory means, the third region being the data storage region;
 - requiring the entry in the card of at least a first keycode for writing in the first and second regions of the memory means;
 - writing one or more keycodes in the first region of the memory means by entering the first keycode and any additional required keycodes; and
 - writing zone definition data in the second region of the memory means by entering the first keycode and any additional keycodes, the zone definition data comprising one or more zone definition words each corresponding to a respective data zone in the third region of the memory means, each zone definition word specifying at least the starting address of the corresponding zone, the size of the corresponding zone and whether no keycode or one or more of the first keycode and the keycode or keycodes in the first region are required to be entered in the card to read data in the corresponding data zone and whether no keycode or one or more of the first keycode and the keycode or keycodes in the first region are required to be entered in the card to write data in the corresponding zone.

18. The method according to claim 17 wherein data is stored in each data zone as successively located data records and each zone definition word further specifies the maximum number of data records that can be stored in the corresponding zone, the length of the data in each data record in the corresponding zone and a zone allocation area in the memory means for storing data indicative of the location of the next data record to be stored in the corresponding zone.
19. In an IC information card containing a non-volatile memory means having one or more data zones each requiring the entry in card of a respective keycode or combination of keycodes for reading data in the data zone and a respective keycode or combination of keycodes for writing data in the data zone, a method for preventing the dissemination of knowledge of the respective keycode or keycodes required for reading or writing in the data zones of the card comprising the steps of:
- storing the respective keycode or keycodes required for reading or writing in the data zones of the memory means of the card in a separate control card; and
 - transferring by two card reader/writer means any required keycode or keycodes from the control card to the card when reading or writing of a selected one of the data zones in the memory means of the card is to be carried out.

INTERNATIONAL SEARCH REPORT

International Application No PCT/US 86/01722

I. CLASSIFICATION OF SUBJECT MATTER (if several classification symbols apply, indicate all) ⁶		
According to International Patent Classification (IPC) or to both National Classification and IPC		
IPC ⁴ : G 07 F 7/10; G 06 F 12/14		
II. FIELDS SEARCHED		
Minimum Documentation Searched ⁷		
Classification System	Classification Symbols	
IPC ⁴	G 07 F; G 06 F	
Documentation Searched other than Minimum Documentation to the extent that such Documents are included in the Fields Searched ⁸		
III. DOCUMENTS CONSIDERED TO BE RELEVANT ⁹		
Category ⁹	Citation of Document, ¹¹ with indication, where appropriate, of the relevant passages ¹²	Relevant to Claim No. ¹³
A	EP, A, 0152024 (TOSHIBA) 21 August 1985, see abstract; figures; page 3, line 28 - page 9, line 20 --	1-4,9,10,12,14,15,17,18
A	US, A, 4211919 (M. UGON) 8 July 1980, see abstract; column 3, line 64 - column 6, line 33; figures 1-4B cited in the application --	1-3,8,9,10
P,A	EP, A, 0190733 (TOSHIBA) 13 August 1986 --	
A	US, A, 4204113 (G. GIRAUD) 20 May 1980 -----	
<div style="display: flex; justify-content: space-between;"> <div style="width: 45%;"> <p>¹⁰ * Special categories of cited documents:</p> <p>"A" document defining the general state of the art which is not considered to be of particular relevance</p> <p>"E" earlier document but published on or after the international filing date</p> <p>"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)</p> <p>"O" document referring to an oral disclosure, use, exhibition or other means</p> <p>"P" document published prior to the international filing date but later than the priority date claimed</p> </div> <div style="width: 45%;"> <p>"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention</p> <p>"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step</p> <p>"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.</p> <p>"&" document member of the same patent family</p> </div> </div>

ANNEX TO THE INTERNATIONAL SEARCH REPORT ON

INTERNATIONAL APPLICATION NO. PCT/US 86/01722 (SA 14428)

This Annex lists the patent family members relating to the patent documents cited in the above-mentioned international search report. The members are as contained in the European Patent Office EDP file on 05/02/87

The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.

Patent document cited in search report	Publication date	Patent family member(s)	Publication date
EP-A- 0152024	21/08/85	None
